Computers through the lens of Mark Richards
THE BEST WAY TO SEE THE FUTURE OF COMPUTING IS TO BROWSE ITS PAST.

The computer. In all of human history, rarely has one invention done so much to change the world in such a short time.

Computer History Museum is home to the world’s largest collection of computing artifacts and offers a variety of exhibits, programs, and events. It’s where computing history lives.

Come visit us and see how far technology has come.

**EXHIBITS**

Innovation in the Valley (now – September 2009)
Mastering the Game: A History of Computer Chess (now – September 2009)
Visible Storage: 600+ Artifacts from the Museum Collection (now – May 2009)
Charles Babbage’s Difference Engine (September 2007 – August 2008)
Timeline of Computing History (opening October 2009)

Rescued treasures:
A curator’s personal account

It was a curator’s dream: a forgotten warehouse filled to the brim with computer artifacts, from Depression-era punch card equipment to mainframes and minicomputers. CHM’s senior curator tells the story of how he and volunteer Alex Bochannek, sponsored by SAP AG, rushed to Dortmund, Germany, to save this collection from destruction. _By Dag Spicer

The IT Corporate Histories Project
Stories bring history to life. With a grant from the Alfred P. Sloan Foundation, the Museum reached out to those who worked at early information technology companies and collected their pioneering tales. _By Luanne Johnson

The Oral History Collection
What was it like to work at Apple in the early 1980s? In this excerpt from the Museum’s Oral History Collection, Bill Atkinson and Andy Hertzfeld, major contributors to the creation of the Macintosh, share anecdotes from the early days of Apple. _By Len Shustek

Why take pictures of computers?
The vision of photographer Mark Richards helps us look at computers in new ways—as representations of their inventors’ ideas and dreams and lives.

“Go off and do something wonderful”
Robert Noyce is best known as the cofounder of Fairchild Semiconductor and Intel. Four stories from the life of Bob Noyce offer glimpses into what made him one of the twentieth century’s most important inventors and entrepreneurs. _By Leslie Berlin

Leslie Berlin is project historian for the Silicon Valley Archives at Stanford University. Her first book, The Man Behind the Microchip: Robert Noyce and the Invention of Silicon Valley (hemanbehindthemicrochip.com), won the 2006 Book Award from the American Association for History and Computing. Leslie holds a PhD in history from Stanford.

Luanne Johnson, cochair of the Computer History Museum Software Industry Special Interest Group, served as principal investigator for CHM’s Information Technology Corporate Histories Project. Luanne has more than forty years of experience in the information technology industry as a programmer, software entrepreneur, and executive with industry-related nonprofit organizations.

Leonard J. Shustek is chairman of the CHM Board of Trustees and a partner in the investment firm VenCraft. The retired cofounder of Network General Corporation (now Network Associates), Len is an occasional consulting professor at Stanford University, where he earned an MS and a PhD in computer science. He is also a trustee of Polytechnic University in Brooklyn, New York, where he earned his BS and MS in physics.

Dag Spicer is senior curator of the Computer History Museum, where he has been since 1996. A former electrical engineer, Dag also holds advanced degrees in the history of science and technology from the University of Toronto and Stanford University.
IN THIS ISSUE

When I was a child, I hated history. It was boring, the teachers made me memorize irrelevant facts, and those facts bore no detectable relationship to my life. If “there is a history in all men’s lives,” as Shakespeare’s Warwick tells King Henry IV, then what’s so special about it?

The answer is that some history has impact. It changes lives. It inspires. It teaches. That is the history we must collect, and we must find exciting ways to present it.

This issue of Core has multiple examples of collecting and presenting history that has impact. It starts with the remarkable story of discovering a previously unknown treasure trove of the raw material of history, in the form of hundreds of important artifacts hidden away in a warehouse in industrial Germany and destined for the scrap heap. They were rescued, thanks to the generosity of SAP AG, in a mission worthy of Raiders of the Lost Ark.

Then on to another form of rescuing history: gathering the stories of pioneers while they are still available to be told. The Sloan Foundation–sponsored IT Corporate Histories Project used equal measures of web-based high technology and old-fashioned human outreach to accumulate valuable materials for historians and researchers to use.

The excerpts from our oral history of Bill Atkinson and Andy Hertzfeld about their experiences at Apple give us insight into a remarkable company culture at a time when established companies were threatened by young upstarts. There is good advice here, too, from how programmers can be great to how everyone should live life.

We have many remarkable heroes in the computer industry. Here Leslie Berlin presents anecdotes about Bob Noyce from her recent biography. Leslie not only shows us various sides of the Intel cofounder’s personality, but also helps us find the lessons we can learn from his successes and failures.

Finally, we pause in the center section to appreciate the visual beauty of the computer and its component parts. There are many ways that computers are used to create art, but photographer Mark Richards shows us that, when looked at through the right lens, computers are art.

We hope you enjoy this issue of Core and, as always, we welcome your comments.

Len Shustek

LAST YEAR’S FELLOWS

Sir Antony Hoare  Robert Kahn  Butler Lampson  Marvin Minsky

Book your next event at a place where even the walls are interesting.

Before you book one more predictable meeting room at one more predictable hotel, here’s an alternative with style and imagination: book it here at the Museum.

Whether you’re having a conference, meeting, or party, the Museum is conveniently located and definitely special. Our unique exhibits can’t be found at any other location. We can easily host up to 1,500 guests. And our staff has the experience to make yours an event that everyone enjoys.

To know more, call +1 650 810 1013 or email: myevent@computerhistory.org

Rescued treasures: A curator’s personal account
On December 8, 2006, the CMA CGM Hugo, three football fields long and one of the world’s largest deep ocean container ships, slipped into its berth at the sunny Port of Oakland.

Among its precious cargo of more than 8,200 forty-foot containers were six holding rare computer artifacts from a warehouse in northwestern Germany on their way to the Computer History Museum in Mountain View, their journey sponsored by software leader SAP AG.

These artifacts were rescued only weeks earlier by a “rapid-response team” composed of Museum volunteer (and native German speaker) Alex Bochannek and me, the Museum’s senior curator.

How did these rare objects make their multi-thousand-mile journey to the Museum and why?

**TRACES OF THE PAST**

This story begins in August 2006, when Siegfried M., a computer programmer and consultant from Dortmund, Germany, notified the Museum about a collection of rare computing objects in a warehouse near him. (For privacy reasons, I use only the initial of Siegfried’s surname.) The warehouse was on the outskirts of Castrop-Rauxel, a small town in an industrial area once rich in coal. The town was bombed with particular vigor by the Allies during World War II as it also had large chemical and explosives complexes—a “double score” for Allied bombers.

History is always present in Europe . . . and even during this mission, sixty or more years after the conflagration, traces of the past were all around us.

We determined that the Castrop-Rauxel warehouse was being used as an informal storage area by Gustav T., who apparently had hoped to establish a German computer museum of his own. Gustav appeared to have acquired a collection of items belonging to a professor at the University of Aachen and combined it with small computer collections from other sources. After some time, Gustav was faced with personal bankruptcy. As a creditor, it was now Siegfried’s intent to have a court-appointed administrator seize the collection and dispose of Gustav’s obligations to him through its sale.

It was at this point that Siegfried contacted the Museum as a possible buyer. We were certainly interested!

Being sensitive to issues of national pride, we ensured that other German museums had had a chance to look over the collection and potentially acquire items for themselves. This “ecosystem” approach is used by most museums to make optimum use of scarce resources. As long as something is preserved in a professionally managed and stable institution, CHM is agnostic about where items ultimately rest.

Siegfried and volunteer Alex Bochannek spoke on the telephone at length about the collection coming to CHM. Siegfried agreed to travel to the warehouse that weekend and take pictures of the collection in situ.

When we received the pictures, we were quite taken aback by the size of the warehouse and the scope of its contents. The warehouse was being shared with a construction equipment operator, and while it did have doors, they were left open all day and the warehouse contents were covered in dust . . . and, in places, bird droppings.
A quick meeting was convened with CHM board chairman Len Shustek, CEO John Toole, and vice president of operations David Dial to discuss next steps, if any. In a letter to the Acquisitions Committee of the Museum, I expressed my optimism at the opportunity:

Alex and I believe this to be an opportunity of enormous scale, diversity, and significance. The Museum has never had such an opportunity in its over three-decade existence to fill existing gaps in the collection, provide spares for possible restorations, obtain duplicate objects for loans or trades, and dramatically enhance the international scope of its collection.

We all agreed this collection had enormous potential and was at least worth a visit to assess it more closely. This was August 4. By noon on August 6, Alex and I were landing in Frankfurt—an airport of jaw-dropping scale—where we rented a car and then headed out onto the autobahn toward Dortmund. We arrived at our hotel in Castrop-Rauxel nearly twenty-four hours after leaving Mountain View.

THE WAREHOUSE

The next morning, Alex and I were to briefly meet Siegfried at the warehouse, which turned out to be a storage building of the German national power company, RWE. We were very excited, not knowing in what condition to expect the building or its contents. Once on site, we checked in with the locals who brought us into the building.

What met us was so overwhelming—so broad, so high, so deep—that Alex and I exchanged incredulous smiles, probably half out of fear, half out of joy. At the warehouse we briefly met Siegfried, a personable man who spoke superb English (like most Germans today), and then returned to the hotel to prepare for the first working day of the visit.

Considerable preparation had been made in advance at the Museum in Mountain View to identify as many items as possible from Siegfried’s initial photographs. Once on site in Germany, Alex and I worked to a 2m-by-2m grid system in which the entire collection (more than 14,000 square feet in area) was divided. The contents of each 2m-by-2m square were recorded in a notebook and included (where possible) manufacturer, model, and any other relevant information. About 20 percent of the collection contained pallets of documents and media (magnetic and otherwise) containing historical software. Some of these documents were unique—site planning documents and sales “requests for proposals” from universities and businesses wishing to bring computers into their organizations. These are rare and offer a great deal of information about business processes and their automation at a time when many organizations were making their first foray into computing.
Most of the collection, however, was hardware—it took Alex and me ten days to survey it—ranging from Depression-era mechanical punch card office machines to mainframes and minicomputers.

While we worked away, after a few days Alex asked what the backhoe operator, who had been working just outside the building near us since we arrived, was doing. He was, to my chagrin but Alex’s bemusement (bravado?), looking for unexploded World War II ordnance. An unexploded 500-lb. bomb had been located only a week before we arrived, about 1,000 feet away from where we were working. As I noted, history in Europe is everywhere, and even here—more than sixty years later near a warehouse in a small town—Allied bombs were still being found.

On Day 5, representatives from the German moving company Hasenkamp visited us to discuss how to ship whatever items we decided ought to be sent on to Mountain View (later indicated by a yellow sticker as Alex and I walked around the collection one final time). When they arrived, they had the same smile Alex and I had had on our first arrival: Was it fear? Disbelief? Amazement? They were to return twice more before we left.

**WHAT TO SAVE, WHAT TO LEAVE**

We now began the most difficult part of the adventure: deciding which items to save and which to leave behind. With a budget already stretched, we had the task of taking “only” seven ocean containers’ worth of cargo. Alex and I had a great deal of support from CHM software curator Al Kossow, who put his research skills to great effect, whether it was looking up obscure German data processing equipment or commenting on the desirability of obtaining particular software. Vice president of operations David Dial was also critical in navigating the intricacies of international freight forwarding. Due to the span of computer history represented by the collection, the thousands of individual objects, the distances, and possible customs issues involved, this team approach was absolutely mandatory for success.

Alex and I displayed Marine-like discipline in not opening boxes at random and exploring their contents—much as we would have liked to! Sadly, on a project of this scale, one must make instant decisions or end up saving nothing. We did allow ourselves fifteen minutes of “unstructured playtime” each day, which we spent opening random boxes as fast as we could in hopes of finding some highly interesting object. We were usually not disappointed. A 1950s Anker-Werke accounting machine (shown on page 8) and a 1960s AEG-Telefunken computer system (pictured on page 9) were just two objects from the rescue mission.

I think it’s a good thing Alex and I did not understand the scope of the collection beforehand or we may have become discouraged. Now, we not only had to arrange for shipping the items we wanted halfway across the world, we had to arrange for proper recycling of the electronic waste from the items we did not retain (mostly common microcomputers). Europe has very strict recycling regulations but, thanks again to Alex, we were able to navigate the shipping and recycling
smoothly. Prior to final recycling, CHM also invited several German computer clubs to look at the items we did not take and to consider bringing them into their own collections.

As Alex and I finished tagging all the items coming to Mountain View on Day 9, we were glad to be leaving the respiratory problems, bird droppings, mold, rat poison, and occasional dead bird behind. We left early the next morning for the return flight to San Francisco.

When the Hugo finally pulled into the Port of Oakland, we were reminded of those days in the warehouse. Now we begin the multiyear process of inventorying and creating catalog records for each of the many thousands of objects in the donation. CHM also moved ahead by a year its planned purchase of off-site warehouse space to accommodate the German donation.

**WORKING AGAINST TIME**

Every day, year after year, the Computer History Museum works against time. Every year many thousands of tons of computer equipment are disposed of in the world’s landfills—a problem unforeseen in the utopian days of early computing. Many of these items are rather uninteresting, mass-produced IBM-compatible machines of which the Museum has sufficient exemplars.

But others are truly worthy of being saved. Although we cannot know absolutely, it seems certain that extremely rare (in some cases unique) items from computing’s early days are in this same waste stream. I say it “seems certain” because the few rescue missions with which CHM has been involved have had outstanding results—but have also left all involved with a feeling of “Wow, that was close!”

This incredible fragility of our world’s material traces—hardware, software, the ideas behind them, the marketing materials, the people involved who can (for a while) be interviewed for an oral history—makes the window for preserving computing history especially narrow. While the delicate nature of artifact discovery and preservation is well known to archaeologists (from whom all museum curators draw some of their DNA), computers present unique challenges—first of which is a form of consciousness raising, so that old computers are not automatically considered to have no value.

Missions like this one are central to the Museum’s purpose of being home to the world’s largest and most important collection of computers and computing-related objects. While some may say CHM was lucky, it has always been my view that luck is merely the intersection of preparation and opportunity. As this German adventure shows, CHM remains prepared to preserve computer history at a moment’s notice.

I would like to dedicate this article to Alex Bochannek, who has volunteered at CHM for ten years and without whose generosity of spirit and language skills this acquisition simply could not have taken place. Alex is also a patient and fun travel companion. The entire Museum also thanks software industry leader SAP AG of Walldorf, Germany, which made an outstandingly big-hearted gift of $250,000 to CHM for the shipping and logistical support of this collection. Thank you both. _Dag Spicer
The “guano sorter” found in the warehouse. Wintering birds were responsible. Fortunately, this level of contamination was found only beneath warm warehouse lights, which were sparsely situated. For occupational health reasons, this item was not retained.

AEG-Telefunken TR 440 computer system (1969). This now rare German mainframe formed part of Germany’s national industrial strategy to develop expertise in computer design systems.

Opportunities to obtain a large collection of museum artifacts are rare, and the financial and preservation responsibilities that go with such initiatives are significant. A most generous gift of $250,000 from global software leader SAP AG helped to provide the required logistical support—as well as to cover shipping and storage costs—for the successful rescue of thousands of artifacts from more than 112 European and international manufacturers, including Telefunken, Siemens, Zuse, Olivetti, and Groupe Bull.

Several of the artifacts will be used to populate the Computer History Museum’s 14,000-square-foot “Timeline of Computing History” exhibit, to be launched in 2009, as well as other future physical and virtual exhibits. The new collection greatly enhances the Museum’s ability to undertake major exhibits, and will provide researchers access to unique technical information unavailable anywhere else.
One summer Sunday in 1973, on David del Rio’s first day of work at Software AG, the phone rang. A client in Los Angeles was having problems with a trial of Adabas, a database management system developed in Germany and distributed by David’s new employer.

Within twenty-four hours, David was on a plane from Virginia to Los Angeles with Dick McGann, an “experienced” Adabas programmer who had been with the company two whole months. David’s promised four to six weeks of training were compressed into an eight-hour flight to California, during which he frantically reviewed documentation—all in German—and asked questions of Dick—usually, “What is this in English?” That night he fell asleep over the manuals, and the next morning he was on site assisting the client.

A COLLECTION OF STORIES
If this story brings a smile to your face, it’s probably because you, too, have a fly-by-the-seat-of-your-pants, scramble-to-deliver-the-goods story to tell. The information technology industry was built by people who hustled to get the job done despite ever-changing requirements, impossible deadlines, and slim lines of support all around. It was hectic; it was exhilarating; it was crazy. You either loved it or you got out.

The IT Corporate Histories Collection (computerhistory.org/corphist) is a repository for these stories and many more materials that preserve the history of information technology companies. The collection was developed by a partnership of the Computer History Museum, the Charles Babbage Foundation, and the Software History Center (subsequently acquired by the Computer History Museum) and funded by a grant from the Alfred P. Sloan Foundation.

Through an initiative to use the Internet to preserve the recent history of science and technology, the Sloan Foundation encourages people to record history by telling their personal stories about working on technology projects. The IT Corporate Histories Collection focuses on stories told by people who worked for companies that developed and marketed information technology in all its permutations. The stories range from pithy anecdotes to in-depth descriptions of a company start-up or new product development. While most are memoirs written by the participants, the collection also includes a number of videotaped interviews.

EXPLODING MYTHS
These stories provide great insights into the history of IT companies. Sometimes they serve to explode long-standing industry myths. For example, many in the IT industry have heard the story that Gary Kildall, the founder of Digital Research, Inc., blew off a meeting with “the suits” from IBM regarding licensing the CP/M operating system to go gal-livanting in his private airplane. Supposedly the frustrated IBM folks turned to Microsoft’s MS-DOS operating system for their PC, and DRI missed out on the greatest opportunity in the software industry.

Claims and counter-claims about this story have floated about for years. But Curt Geske was there. In his story “DRI and IBM—First Meeting,” Geske tells us the meeting was a rather mundane affair between Dorothy Kildall, who ran the business end of things, and IBM lawyers over the wording of a nondisclosure agreement. IBM made it known that Microsoft already had a contract to do the work and expected DRI
to supply them with the full source code for CP/M, which DRI was understandably reluctant to do. DRI and IBM did eventually reach an agreement for IBM to distribute CP/M, but as recounted in Steve Maysonave’s videotaped story, the agreement was structured in a way that gave all the advantage to Microsoft. The outcome was consistent with the legend, but it hinged on the intricacies of contract negotiations rather than on Gary’s preference for flying over attending meetings.

**REVEALING INSIGHTS**

Other stories in the collection support long-held beliefs. In the 1960s and 1970s, entrepreneurs had many war stories about how IBM—the “evil empire” of the time—was out to crush them. This was a persistent legend that was difficult to authenticate because IBM never had an official objective to crush competition. But stories from those who were there reveal how hard it could be to compete against a company that had such strong market dominance and controlled its customer accounts so effectively.

In “Day One at SAGNA,” Michael Jakes recounts how a client refused to allow him to make copies of a report from a database selection committee that chose Software AG’s Ada-bas over IBM’s product. The client was so fearful of reprisals from IBM if the results of an analysis unfavorable to IBM leaked out that he allowed Michael, hidden in a conference room, only an hour to make as many handwritten notes as he could.

In another story, “MRX 1270 Terminal Control Unit,” Robert DiMenna describes how IBM engineers provided incomplete interface specifications for their System 360/370 computers, and how the IBM salesmen exaggerated the risks of attaching non-IBM equipment to their computers, thereby retarding sales of the Memorex 1270. Clearly the competitive obstacles were real, whether they were the result of official IBM policies or simply the fallout of IBM’s very focused marketing strategy.

**REACHING OUT FOR MEMORIES**

Because collecting personal stories was a key objective of the Sloan initiative, developing this collection required extensive outreach to find people who worked for these companies. The stories resulting from this effort are valuable historical source materials. Moreover, the outreach effort resulted in the collection of a large number of documents and other artifacts related to these companies—more than 1,500 documents in the online collection plus hundreds more donated to the Museum archives. The vast majority of these materials came from the personal files of individuals, not from corporate files. Because most of the companies covered by the project are defunct—long since acquired or otherwise out of business—the materials collected from the basements and attics of the participants represent historical information that was at risk of being lost forever.

More than 250 people have contributed everything from handwritten notes to organization charts to marketing brochures to network schematics—the whole hodgepodge of materials that employees of these companies saved for whatever reasons were important to them at the time. The Cincom collection includes marketing materials from the late 1960s that explain to potential customers what a database is and why you need one. Compare that to the Informix marketing brochure from the mid-1990s, which tells a fanciful tale of how Napoleon used the Informix OnLine DBMS to win the battle of Waterloo. In the intervening decades, database marketing materials had shifted from explanations of what the product was to attention-getting tactics.

The materials collected are critical to documenting the history of the industry that began to transform the world in the last half of the twentieth century. Thanks to the IT Corporate Histories Collection, they are being preserved to enlighten and inspire many generations to come.
For many years the Computer History Museum has had an active program to gather videotaped histories from people who have done pioneering work in this first century of the information age. These recordings are a rich aggregation of stories that are preserved in the collection, transcribed, and made available on the web to researchers, students, and anyone curious about how invention happens.

The oral histories the Museum collects are conversations about people’s lives. We want to know about their upbringing, their families, their education, and their jobs. But above all, we want to know how they came to the passion and creativity that leads to innovation.

Here, as an example, are excerpts from an interview conducted by Grady Booch on June 8, 2004, of Bill Atkinson and Andy Hertzfeld, who were major contributors to the creation of the Apple Macintosh.¹

I came to Apple in 1978. I was hired as the application software department, because there wasn’t one. Actually, at the time I was a little better at pushing chips than software, but that’s what they needed. So, okay, I can do that.

There is a famous legend that the Apple team visited Xerox PARC (Palo Alto Research Center) and carried away the user-interface ideas. What really happened?

Atkinson: In 1979, when the Lisa team went to visit, we got to see the Alto and the Smalltalk System and I think the Bravo text editor. What people misunderstand is that we didn’t just copy what we saw. It gave us great inspiration and gave us great confidence that, yes, we did want to do windowing, but then we had to go incrementally, evolutionary-wise, and develop this user interface a piece at a time by a lot of trial and error and a lot of stupid mistakes.

What really helped us was user testing. Larry Tesler was big on this. We wanted a beginning person to walk up and be able to figure it out. We’d give them tasks and say, “Here, edit this document and save it,” and asked them to mutter a stream of consciousness. What are they thinking about? That was very important because why they do something is just as important as what they do. Thousands of these kinds of tests where you find that people made mistakes are what led us to the user interface.

The Mac project was run very differently from—and almost in competition with—the Lisa that had been started years earlier.

Hertzfeld: The early 1980s were the Gold Rush days for the personal computer. We want to learn about the atmosphere of the time. There was, everyone says, something different about Apple.

Hertzfeld: The first computer I owned was an Apple II, serial number 1708, which I bought in January 1978. I wanted my own computer and checked out the Altairs and the IMSAIs, but I wasn’t handy enough with a soldering iron. When the Apple II happened, I knew it was for me. I was a grad student at UC Berkeley, but it quickly just took over my life.

I wasn’t an Apple employee then. I was one of those people who were led to Apple like a moth to the flame; the Apple II attracted me to Apple. I started at Apple in August of ’79.

Atkinson: The thing that drew me to Apple was this notion that you can do something with your life. Making a dent in the world is what Steve Jobs used to call it. You can have an impact for the positive if you are where things are being created.

¹ Oral histories are not scripted, and a transcript of casual speech is very different from what one would write. I have taken the liberty of editing and reordering freely for presentation. For the original transcript, see: archive.computerhistory.org/search/oh.
was the immediate predecessor of the Macintosh hardware, not the Lisa. Lisa had seven different applications all developed by Apple, which was another way the Lisa team diverged from the Apple II. One of the characteristics of the Apple II was the third-party market. But you get a different spirit. The Mac brought it back home. It combined the Apple II spirit and a thriving third-party community. And Burrell and Woz are similar-type designers: the crazy genius instead of the conservative committee.

A T k I N S o N : The goals of the two were very different. We were designing the Lisa for an office worker, and since we weren’t office workers ourselves, it was kind of hard to know exactly what they wanted. When the Mac was designed, I think we had a pretty clear picture of a fourteen-year-old boy using this thing, and we knew what they were like.

Every company has a unique culture for writing software. What was the Mac culture?

H E R T Z F E L D : Freewheeling. Bill was really the center of coming up with the user interface, but he worked at home so he would come in maybe two or three times a week, usually when he had discovered something new. We would all gather around and talk about it and give him feedback.

A T k I N S o N : I’d get good suggestions from other people and say, “Oh, that’s a good idea.”

H E R T Z F E L D : It was very loose. In the Lisa group there were a lot more philosophical arguments about what is the best way to do it in the abstract. With the Mac, it was much more, “Try it out and see how it feels,” every step of the way.

Gardner Hendrie

The founder and chair of the Oral History Committee at the Museum is Gardner Hendrie, who tackled that project like everything he does: comprehensively and in depth. He bought multiple sets of equipment, funded the necessary staff position, took a course in how to do oral histories, and for the last five years has been either videographer or interviewer (or both!) for at least a third of the more than 120 oral histories the Museum has done in locations all over the country.

Amazing as it sounds, this is only a small part of Gardner’s contributions to the Museum. Gardner has been a trustee for more than twenty years, starting back when CHM was The Computer Museum in Boston. He is on the Executive and Finance Committees, for which he flies out from Boston every month. He is chairman of both the Exhibits and Investment Committees and has recently reinvigorated the Major Gifts committee. He personally gives at the highest level each year to the Annual Campaign and has made a multimillion-dollar contribution to the Museum Campaign. He funds special projects whenever he sees the need.

Gardner is a computer pioneer himself. He was the designer of several early minicomputers and was one of the founders of Stratus Computer Inc. Since 1985 he has been with Sigma Partners, a venture capital firm, and has served on many of their portfolio companies’ boards.

For the last ten years Gardner has been my mentor and role model for energetic involvement. One of the great pleasures in being chairman of the Museum is the opportunity it provides to work with Gardner, and I thank him profoundly for that. —Len Shustek

But creating software is about more than writing programs that work.

Atkinson: It’s an art form. It’s not just practical: “Does it do the job?” But is it clean inside? I would spend time rewriting whole sections of code just to make them more cleanly organized, more clear. I’m a firm believer that the best way to prevent bugs is to make it so that you can read the code and understand exactly what it’s doing.

That was a little bit counter to what I ran into when I first came to Apple. There were a lot of people who prided themselves on how this little piece of code does something magic. I found that if I spent time going over the code, cleaning it up, making it sometimes tighter, but also making it so that it was straightforward for another person to follow in my footsteps, then I would feel proud of it.

Hertzfeld: Pick things to work on that you really, really want to use yourself. You can close the loop with the user testing, but if you are one of the users, you can just iterate in your head. Of all the things you can work on, work on the thing that isn’t in the world that you want to make be in the world. Then you can be both user and creator. There is real power in that. To some extent, that’s the secret of the Mac’s success. We all wanted the Mac more than anyone else. So much so, that we had to make it.

Follow your heart. You have to do work each day that you believe in.

And that, my friends, is advice that applies to more than just writing software.

My First Computer(s)

My first desktop computer (1982) was put together by San Francisco engineer and philanthropist Henry Dakin, who has helped many people in the nonprofit sector become computer functional. It consisted of a custom DOS-based computer, two eight-inch Shugart floppy drives, a big black-and-white CRT, and a dot-matrix printer. My first husband was an editor at the *San Jose Mercury News*, and the Merc outfitted its staff with TRS-80 laptops to cover the 1984 Democratic National Convention in San Francisco. I looked at his TRS-80 and said, “That’s neat!” And got one for myself.

Dr. Gloria C. Duffy
President and CEO
The Commonwealth Club of California
Why take pictures of computers?

Imagine we could be around during the time of the first printing press. What would you want to keep for civilization to see in the future? This is one of the questions I asked myself as I photographed these computers. I set out to document what I saw as the visual elements of the beginning of a new era, the age of the computer, a time as significant as the age of the early printing press.

I wanted my photography to express the kind of passion that men and women felt when they were inventing these machines. More than just taking pictures, I wanted both the layperson and the computer professional to feel what I felt. To see these machines as more than steel and wire and plastic. To see that these are ideas and dreams and lives.

As a still photographer I can use only two dimensions, color, form, context, and a few other tricks. I must use them with my enthusiasm and my imagination, while staying true to the machines. My hope is that my photographs will allow people to see these machines in a new way. _Mark Richards

Mark Richards has photographed diverse human subjects, from combat in Afghanistan for Time to street gangs in Los Angeles for Newsweek. A California native, Mark has covered Silicon Valley since the early 1990s. His images have earned numerous awards from Communications Arts magazine, and his work has appeared in publications such as the New York Times Sunday Magazine, Fortune, Smithsonian, Life, and BusinessWeek.

These pictures are from Core Memory: A Visual Survey of Vintage Computers (Chronicle Books, 2007), which features Mark’s photographs of machines from the collection of the Computer History Museum with text by John Alderman. Core Memory presents “a guided tour through some of the most notable and curious devices in the history of computing.” The book is available in the Museum gift shop or by contacting Jim Somers at somers@computerhistory.org. The price for Museum members is $30, including tax. The book’s list price is $35.

“Go off and do something wonderful”

FOUR STORIES FROM THE LIFE OF ROBERT NOYCE // BY LESLIE BERLIN

Bob Noyce (left) and his older brother Gaylord proudly display the glider they built in the summer of 1945.
Robert Noyce was called the Thomas Edison and the Henry Ford of Silicon Valley: Edison for his coinvention of the integrated circuit, a device that lies at the heart of modern electronics; Ford for his work as a cofounder of two companies—Fairchild Semiconductor, the first successful silicon firm in Silicon Valley, and Intel, today the largest semiconductor company in the world. Noyce also mentored dozens of entrepreneurs, an effort he loved and called “restocking the stream I fished from.”

Right up until his death in 1990 at the age of sixty-two, Noyce was a daredevil. His jacket bore a patch that read, “No guts, no glory.” It was a fitting motto for a man who flew his own jets and took time off every year to go helicopter skiing. It is no wonder, then, that for many his life encapsulated the high-flying, high-risk, high-reward world of high technology.

It is impossible to do justice to Noyce in a brief article. Instead, I offer four stories that provide glimpses into what made him one of the twentieth century’s most important inventors and entrepreneurs. And in the spirit of Noyce’s belief that the best knowledge is knowledge that can be used, each story includes a “take-away” for readers.

BOYHOOD ADVENTURER

When Noyce was twelve, he and his fourteen-year-old brother Gaylord decided to build a boy-sized glider. They used no blueprints, only the knowledge they had gained from years of constructing model airplanes.

Building the glider was the highlight of the summer of 1940 for many of the seventeen children Bobby Noyce convinced to help in the effort. A boy whose father’s furniture store received rugs on long bamboo spindles donated the rods for the glider’s frame. A girl sewed the cheesecloth that stretched over the wings. And the boy with the newly minted driver’s license was charged with hitching the glider to the back of his father’s car to see if the plane could be flown like a kite.

But for Bobby Noyce, the real test of success would be if he could, as he put it, “jump off the roof of a barn and live.”

He was only aloft for a few seconds, but he landed without crushing the machine and declared the experiment a success.

TAKE-AWAY. Noyce, at age twelve, already possessed three attributes that would define his future success as a technical entrepreneur. First, his technical ability with his hands is evident. Throughout his life, Noyce was respected by engineers as well as scientists because he was not simply a thinker; he was also a builder. Second, the adolescent Noyce pulled together a diverse team, each member of which he tapped for his or her ability to contribute something unique to the project. Finally, in the boy who reached the edge of the roof and kept on running, we see the soul of the man who lived without limits, a man who believed that every idea could be taken further. These three attributes—technical credibility, the ability to assemble and motivate a diverse team, and a “no limits” mindset when it came to goal-setting—underpinned Noyce’s technical and business success.

For Bobby Noyce, the real test of success would be if he could, as he put it, “jump off the roof of a barn and live.”

SCIENTIST TO MANAGER

In September 1957, Noyce, then thirty years old, joined a rebellion led by seven of his coworkers. Julius Blank, Vic Grinich, Jean Hoerni, Eugene Kleiner, Jay Last, Gordon Moore, and Sheldon Roberts had met more than a year earlier when they were hired by William Shockley, co-inventor of the transistor, to work at his new company in Mountain View.

In short order, Shockley proved an unpredictable micromanager. Even worse, he wrenched the company’s focus away from silicon transistors, the broad market for which was apparent even at that time, to four-layer diodes that were difficult to build and served a limited market. The group of seven, soon joined by Noyce, decided to leave.

It was not easy to find someone willing to fund a start-up company managed by young technologists in 1957, but with the help of two New York bankers (one of whom was Arthur Rock), the group did so. Fairchild Camera and Instrument agreed to back the fledgling operation, Fairchild Semiconductor, and soon acquired it outright.

Noyce headed research and development at Fairchild Semiconductor. He adopted a hands-off management style that encouraged outside-the-box thinking, creative freedom, and collaboration. He was an excellent supervisor of technical work.

In January 1959, Noyce became general manager of Fairchild Semiconductor. A PhD physicist with no formal business training, Noyce taught himself business skills over the next eight years. Within a decade of the company’s founding, Fairchild Semiconductor had 11,000 employees and $12 million in profits. For a while, its parent company (essentially all of whose profit came from the semiconductor division) was the best-performing stock on Wall Street.
Then everything fell apart. Fairchild began missing scheduled deliveries. Products in the development stage could not be successfully transferred to manufacturing. The trickle of employees leaving Fairchild in recent years became a flood. In the third quarter of 1967, profits were 95.5 percent lower than a year before.

Fairchild Semiconductor declined for many reasons, but Noyce himself must bear some responsibility. His laissez-faire management approach—offering general directives rather than following up on specific process details—was ideal for inspiring and supervising highly creative technical work, but this management style did not translate well to large, multifaceted organizations.

**TAKE-AWAY.** Inspirational leadership alone is not effective management. At times, the same person can be both an excellent big-picture, rally-the-troops leader and an outstanding detail-oriented manager, but this management style did not translate well to large, multifaceted organizations.

Noyce’s experiences at Fairchild forced him to recognize his own shortcomings. “One thing I learned at Fairchild,” he later admitted, “is that I don’t run large organizations well. I don’t have the discipline to do that, have the follow through.”

When Noyce and his Fairchild cofounder Gordon Moore left the company in July of 1968 to start a small memory operation that today is called Intel, they deliberately split power evenly between them. This decision, which came directly from Noyce’s having confronted his own managerial limitations at Fairchild, offers yet another take-away: Noyce was willing to act on the knowledge of his own professional limits.

**INVENTOR**

Of the seven patents Noyce filed in his first eighteen months at Fairchild, the best known is #2,981,877 for “Semiconductor Device-and-Lead Structure.” Fairchild called the product developed on the basis of this patent—a complete electronic circuit built on a chip of silicon small enough to be carried off by an ant—a “monolithic integrated circuit.” Nearly every electronic device today contains descendants of the integrated circuit in Noyce’s patent application.
By the time Noyce’s patent application was submitted, however, Noyce himself had left the lab—and research science—for good. As general manager of Fairchild Semiconductor, his primary contribution to integrated circuit development came through his funding relevant research and encouraging gifted researchers. It was not Noyce but a team led by his cofounder Jay Last and anchored by men such as Isy Haas, Bob Norman, Lionel Kattner, and Jim Nall that transitioned Noyce’s notebook entry from good idea to real product. And in truth, Noyce’s patent did not provide much guidance. It said that it ought to be possible to build integrated circuits using isolation techniques as well as the breakthrough planar process invented by Noyce’s Fairchild cofounder Jean Hoerni. The patent did not, however, say how to make this possibility a reality. That was what Last’s group figured out through their own remarkably innovative work, some of which earned team members patents on their own key ideas and processes.

**TAKE-AWAY.** Innovation is rarely the product of a single mind. Invention is best understood as a team effort, with the person ultimately called “inventor” occupying much the same space as the pitcher who has just had a perfect game. The outfielders might have caught a dozen fly balls, the first baseman might have nearly broken his neck to step on the bag an instant before the runner, the catcher might have called for pitches perfectly calibrated to each batter’s weakness, but the record books note only that the pitcher threw a perfect game.

Noyce never hesitated to admit that his ideas about integrated circuits relied heavily on ideas that were “in the air” in 1958 and 1959. Without Hoerni, without Moore, without the work of Kurt Lehovec at Sprague, Noyce never would have imagined the integrated circuit in the way he did. Without Last, the microcircuits group at Fairchild, and other people around the world working in the field, Noyce’s ideas would never have become marketable products.

**MENTOR**

After Noyce retired as Intel board chair in 1979—he remained a board member until his death—he enjoyed mentoring young entrepreneurs. Noyce worked with dozens of youthful technologists and funded many small companies. The best known of the entrepreneurs he encouraged was Steve Jobs, cofounder and CEO of Apple and cofounder of Pixar, Inc.

The two met in 1977, when Apple was a year old. Noyce’s wife, Ann Bowers, headed human resources at Apple, and through her, Jobs deliberately sought out Noyce as a mentor. “Steve would regularly appear at our house on his motorcycle,” Bowers recalls. “Soon he and Bob were disappearing into the basement, talking about projects.”

Noyce answered Jobs’s phone calls—which invariably began with, “I’ve been thinking about what you said” or “I have an idea”—even when they came at midnight. At some point he confided to Bowers, “If he calls late again, I’m going to kill him” . . . but still he answered the phone.

“He was very interested in—fascinated by—the personal computer, and we talked a lot about that,” Jobs recalls of Noyce.

For his part, Jobs believed that “you cannot understand what is happening today without understanding what came before,” and Noyce gave him a way to experience what Jobs called “that second wonderful era of the valley, the semiconductor companies leading into the computer.”

**TAKE-AWAY.** There is an informal sort of generational succession in Silicon Valley that places Noyce near the top of the family tree. A few years ago, for example, the founders of Google asked Steve Jobs for advice and mentorship in the same way Jobs had come to Noyce when Apple was young.

Noyce believed that would-be entrepreneurs needed successful role models (though he never would have put it that way). His financial success directly benefited the entrepreneurs whose companies he funded as an informal angel investor, but the stories about his success indirectly inspired many more who thought, “If he can do it, I can, too.” This belief is an essential aspect of any innovative culture because it encourages new ideas and risk-taking—and with it engenders a self-perpetuating cycle of entrepreneurship. “Optimism is an essential ingredient for innovation,” Noyce—who often advised people to “go off and do something wonderful”—once said. “How else can the individual welcome change over security, adventure over staying in a safe place?”

“All images courtesy of Stanford University Libraries, Department of Special Collections.
This 1965 prototype is early evidence of a novel concept in retailing that looks very familiar from our 2007 perspective. Want to bring your merchandise to potential ready-to-buy customers? Allow customers to compare products and services among vendors? Save them time? Allow them to shop from an armchair? Eliminate traffic congestion? These are not web-based ideas. They are just some of the advantages the Slide-a-Mat Retailing System offered—thirty years before the World Wide Web.

The Slide-a-Mat consisted of a custom desk with two rear-projection screens (with slide projectors inside), one of which showed a product or service and the other of which showed additional information such as specifications. If customers wanted to buy, they pushed one of the buttons running along the edge of the desk to specify the product, color, size, and other features.
To enable customers to place orders, the Slide-a-Mat included a telephone with an optical sense card reader and a set of cards. When ready, the customer slid a vendor-specific plastic card into the telephone, which then dialed the vendor and connected the customer to a salesperson.

The Slide-a-Mat was patented, but internal problems led the company to go under. This prototype is the only physical trace of the system in existence. _Dag Spicer_
Starting in the 1940s, IBM became a major producer of films used for training, documenting business processes, entertaining at company functions, and educating the public. Several IBM films were made by respected filmmakers and sometimes featured well-known actors such as Bob Newhart.

The film *Man & Computer*, made by IBM’s UK branch in 1965, provides a basic understanding of computer operations. A large portion of the film shows the ways in which a computer can be simulated by five people using the standard office equipment of the day. The film employs a number of different techniques, including animations, and features a few brief scenes of an IBM System/360 in use—just months after the first machines were delivered.

*Chris Garcia*
On April 7, 1964, IBM made the most dramatic announcement in computer history. After investing nearly $5 billion in research and development, IBM had created a family of computer models that spanned a 40:1 performance range—and could all run the same software. This family of machines was known as the “System/360,” an allusion to the system covering all points of the customer compass, from a small business doing payroll to a university undertaking scientific research to government agencies processing millions of checks per month.

Even though it was already the market leader in punch card equipment and “electronic data processing machines,” this was a remarkable gamble by IBM.

After supporting seven mutually incompatible computer lines for years, IBM developed the System/360 as a means of simplifying their computer offerings for salespeople and customers alike. The System/360 was supremely successful. Its architecture dominated the mainframe computer industry for more than three decades and can still be seen in various IBM mainframes. IBM sold more than $100 billion worth of System/360 installations over the life of the family—a remarkable milestone, even by today’s standards.

These sales models were used in two ways: first, as part of the presentation made by an IBM salesperson to potential customers; second, as a tool for planning computer installation and layout of the room where the computer would eventually reside.

_Dag Spicer_
Hubert Dreyfus, a professor of philosophy at MIT in the 1960s, found that many of his students thought artificial intelligence (AI) was an already accomplished fact. This misplaced faith helped shape Dreyfus into an early critic of AI’s claims, and in 1965 he was hired by the think tank the RAND Corporation to explore the issue. The result was a ninety-page paper questioning the computer’s ability to serve as a model for the human brain and asserting, for example, that no computer program could defeat even a ten-year-old child at chess.

Two years later Richard Greenblatt, formerly an undergraduate at MIT, wrote a chess program using only 16K of memory for the DEC PDP-6 computer. The program, MacHack VI, played chess at a level far above its predecessors, a factor that would surprise Dreyfus (and the AI community) when demonstrated.

With some confidence, students at MIT challenged Dreyfus to play a game against MacHack VI. Dreyfus lost and the game became a milestone moment in AI—at least for AI proponents.

In fairness to Dreyfus, 1960s computers were primitive ancestors of today’s machines, so to claim computers could think does indeed seem grandiose, even from today’s perspective. After fifty years of research, one of the key conclusions of AI is that, for machines, simple things (e.g., tying a shoe) are difficult and difficult things (e.g., playing chess) are simple. __Kirsten Tashev

Can the machine, the robot, the computer replace man? Can man’s behavior be formalized, his brain and body bypassed, to arrive at the essence of rationality? Is artificial intelligence possible? __Hubert Dreyfus, 1972
The transition of an invention from the laboratory to the marketplace, often difficult, is a process nearly every technology-based company must go through at some stage. In 1946, Presper (“Pres”) Eckert and John Mauchly, inventors of the ENIAC computer at the University of Pennsylvania’s Moore School of Engineering, wanted to form their own company but were constrained by their agreement with the university over patent rights to the EDVAC, ENIAC’s successor.

In his resignation letter, Eckert writes:

I have felt that the patent rights which have been assured me in connection with my work up to this time were an important part of my remuneration...it seems sensible at this time to resign, since...our commercial ideas for computing machines are incompatible with the Moore School’s development program.

Eckert and Mauchly founded the Electronic Control Company (ECC), which became the Eckert-Mauchly Computer Corporation (EMCC) in 1947. With the death of their main financial backer only two years later, Eckert and Mauchly sold their business to the Remington Rand Corporation. For this they received $200,000 and a guarantee of eight years of employment. Their first commercial computer, the UNIVAC I, was delivered to the United States Census Bureau on March 31, 1951.

Although their own business failed, leaving an opening for Remington Rand, Eckert and Mauchly remained pioneers in the development of large-scale electronic computing systems.

TELEBIT MODEM Prototype
DATE: 1980
COLLECTION: OBJECTS
SOURCE: GIFT OF ERIC SMITH
CHM#: X3570.2006
Prototypes fulfill an important part of the Museum’s mission to explore the deeper forces underlying technological innovation. Often a prototype can show the genesis of an important idea or a “road not taken” before the object stabilized and came to market. This modem prototype represents the beginning of the company Telebit, which offered modems based on a new approach to data transmission over noisy lines. Telebit was founded by Paul Baran, a CHM Fellow (2005), and was later acquired by Cisco.

ITR TIME CLOCK
DATE: 1916
COLLECTION: OBJECTS
SOURCE: GIFT OF LEN SHUSTEK
CHM#: X3854.2007
International Time Recording Company (ITR) was founded in Endicott, New York, in 1889. It sold time clocks based on the 1888 patents of Willard Bundy. According to an original sticker located inside this particular unit, the time clock was shipped to R. Wallace & Sons Manufacturing Company of Wallingford, Connecticut, in 1916.

ROBOTS
DATE: 1970s–1980s
COLLECTION: OBJECTS
SOURCE: GIFT OF MONROE H. POSTMAN
CHM#: X3806.2007
By the mid-1970s, the microprocessor was inexpensive enough to place into toy and educational robots, which soon proliferated as often-whimsical links between the fearful imaginings of Shelley’s Frankenstein and more sedate versions of robots as helpers. Often these robots simply integrated technologies into an android shell: many had cassette or eight-track tape players as well as home console video games built into them.

PUNCH CARD CHRISTMAS WREATH
DATE: 1962
COLLECTION: EPHEMERA
SOURCE: GIFT OF CAMILLE BOUNDS
CHM#: X3612.2007
Among the rarest things in the Museum’s collection are “unofficial” objects created by computer users. This wreath, for example, was made over the Christmas holidays in 1962 using IBM punch cards. Its maker, a CalTech student, sold such wreaths to put himself through school. Due to its age and fragility, this wreath may be the only one of its kind.

TEMPLE OF APSHAI, AUTOMATED SIMULATIONS, INC.
DATE: 1981
COLLECTION: SOFTWARE
SOURCE: GIFT OF PHIL ROOT
CHM#: X3671.2007
Temple of Apshai was a computer role-playing game released for many platforms, including the IBM PC (the PC version is shown here). The game was inspired by role-playing board games of the 1970s such as Dungeons & Dragons. Temple of Apshai was followed by two sequels: Gateway to Apshai and Hellsfire Warrior.
In 1821, inventor and mathematician Charles Babbage was poring over a set of mathematical tables. Finding error after error, Babbage exclaimed, “I wish to God these calculations had been executed by steam.” His frustration was not simply at the grindingly tedious labor of checking manually evaluated tables, but at the daunting unreliability of those tables. Science, engineering, construction, banking, and insurance depended on tables for calculation. Ships navigating by the stars relied on them to find their position at sea.

Babbage launched himself on a grand venture to design and build mechanical calculating engines that would eliminate errors. His bid to build infallible machines is a saga of ingenuity and will, which led beyond mechanized arithmetic into the entirely new realm of computing.

Though Babbage was not able to realize his dream of building a mechanical calculating machine, his vision was finally achieved in 2002 when the Science Museum of London completed the first full-sized Babbage Difference Engine. Over the past three years a duplicate engine, along with a printing apparatus, was built. The Babbage engine weighs five tons and consists of 8,000 parts. It is an arresting spectacle in operation.

This machine will be on display at the Computer History Museum for one year, beginning in September 2007. Guest curator Doron Swade, formerly of London’s Science Museum, will be scheduling lectures both about Charles Babbage and about the Science Museum’s task of building the Difference Engine. Throughout the year, CHM staff and volunteers will be demonstrating the machine, and an online exhibit will provide more information about Babbage and the Difference Engine.

For more information about lectures, demonstration schedules, and other events, call +1 650 810 1010 or visit: computerhistory.org.

Donald Wilson—November 25, 2006
LexisNexis developer

Richmond—January 2, 2007
Electronic design automation and integrated circuit design pioneer

Jean Ichbiah—January 26, 2007
Principal designer of Ada programming language

Neil Lincoln—January 26, 2007
Supercomputing architect and pioneer

Jim Gray—January 29, 2007
(missing at sea)
Database pioneer

Doug Ross—January 31, 2007
CAD and software methodology pioneer

Ken Kennedy—February 7, 2007
High-performance computing pioneer

John Backus—March 21, 2007
FORTRAN team leader

Karen Spärck Jones—April 4, 2007
Pioneer in AI and natural language processing

Alan Kotok—May 26, 2006
Computer pioneer, architect, programmer

Bernard Galler—September 4, 2006
Computer pioneer, educator, founding editor, Annals of the History of Computing

Ray Noorda—October 9, 2006

We are saddened to report on the passing of these computer pioneers since January 1, 2006.
**CROSSWORD PUZZLE**

**ACROSS**

1. IBM System/360 artifacts used as sales and planning tools.

4. Slide-based browsing system.

7. Initials of the company that made the recently donated time clock.

8. IBM UK's film "Man & 

14. Temple of 

15. "The early 1980s were the ___ days for the personal computer" (two words).

16. Board member profiled in this issue.

17. German moving company that assisted with the SAP collection.

**DOWN**

2. California port city where the SAP collection arrived.

3. Telebit was founded by CHM Fellow Paul 

5. MIT professor defeated by MacHack VI.

6. "Often a ___ can show the genesis of an important idea or a 'road not taken.'"

8. The first UNIVAC was sold to the United States 

10. A CalTech student sold a punch card 

11. "Day One at _____."

13. The Atkinson and Hertzfeld Oral History was conducted by Grady 

---

**IN THE COLLECTION**

4,000 linear feet of documents (or 12 million pages)

5,000 videos and films

5,000 software titles

20,000 photographs

20,000 objects and ephemera

---

**CHM BY THE NUMBERS**

$77,346,995 donated to the Museum Campaign. Only $47,653,005 to go!

**IN THE COLLECTION**

4,000 linear feet of documents (or 12 million pages)

5,000 videos and films

5,000 software titles

20,000 photographs

20,000 objects and ephemera

**SINCE MOVING TO OUR PERMANENT BUILDING IN 2003**

4 million visitors to the Museum’s website

29,692 tour attendees

2,263 Museum members

671 people who have volunteered

473 events held with 69,955 attendees

123 oral histories recorded

53 lectures held with 15,038 attendees

27 staff additions

16 new Fellows

---

HELP US PRESERVE THE INFORMATION AGE BEFORE ANYBODY FORGETS IT.

BECOME A MEMBER

Today, people take technology as much for granted as the air they breathe. It’s the mission of the Museum to preserve the remarkable history of technology and to celebrate the accomplishments of the extraordinary people who have done so much. As a member, you’ll help us preserve our heritage. And you’ll enjoy a number of benefits, including:

- Complimentary admission to the Museum’s speaker series and speaker receptions
- Discount admission to special Museum activities
- Member email announcements
- Subscription to Core magazine
- Museum memento
- And more

Call +1 650 810 1883 or join online at: computerhistory.org

VOLUNTEER

Help us explain technology to the outside world. This is a perfect opportunity to share your knowledge and your enthusiasm for computers. As a Museum volunteer, you can help in building the collection and restoring computing artifacts. You can assist with lectures, receptions, tours, and special events, or help us with administration and operations. In the process, you’ll also interact with industry leaders, expand your knowledge of computer history, and enjoy the satisfaction of helping us build a world-class museum and research institution.

To learn more, call +1 650 810 1027 or visit us online at: computerhistory.org/volunteers
Who are these people and what computer is that?

Take your best guess! The first three *Core* readers who submit correct answers after July 1, 2007, will receive a free copy of *Core Memory: A Visual Survey of Vintage Computers.*

The fourth and fifth correct submissions will receive Computer History Museum posters. Email your guess to: editor@computerhistory.org. Good luck!

**Last issue’s mystery item** was a rope memory unit from the Apollo Guidance Computer. Congratulations to Brian Knittel, Mike Albaugh, and Randy Neff for correctly identifying it. Each of these lucky people will receive a “25th Anniversary of the Microprocessor” poster.

Rope memory is a special form of magnetic core memory (“core”). While core is useful for storing temporary or changing results, rope memory is a form of read-only memory (ROM) that will keep its contents even in the absence of power. This quality made it particularly attractive as a means of storing the various control programs for the Apollo spaceflight. It was also a very dense form of memory, though brittle and extremely difficult to manufacture. This particular unit was made by Burroughs.
